INTRODUCTION — Dilation and curettage (D&C) is a procedure in which material from the inside of the uterus is removed through the cervix, the lower part of the uterus that opens into the vagina. "Curettage" refers to the scraping or uterine cavity (endometrium) with a surgical instrument called a curette. Some curettes are sharp while others use suction.

REASONS FOR D&C — There are a number of reasons a D&C might be performed. In some cases, the procedure is used to diagnose a medical condition (called diagnostic D&C). In other cases, the procedure is used to treat a medical condition (called therapeutic D&C).

Diagnostic D&C — The primary reason for a diagnostic D&C is to obtain samples of the endometrium to evaluate abnormal cells found during routine screening for cervical cancer. (See "Patient information: Screening for cervical cancer").

In most cases, a healthcare provider will try to obtain a tissue sample with an office procedure called endometrial biopsy. If biopsy is not possible or insufficient tissue is obtained. When this occurs, D&C must be done to obtain an adequate tissue sample. Diagnostic D&C is usually done with hysteroscopy; this involves dilating the cervix and inserting a small instrument that allows the physician to visualize the inside of the uterus. The images are displayed on a monitor, allowing the physician to avoid missing small polyps and ensures that the most visibly abnormal areas are sampled. (See "Patient information: Abnormal uterine bleeding").

Examination of the endometrial tissue by a pathologist can help establish certain diagnoses, including endometrial (uterine) precancerous conditions of the lining of the uterus (endometrial hyperplasia).

Therapeutic D&C — Therapeutic D&C is done to remove the contents of the uterus in the following circumstances:

Miscarriage — In some miscarriages, the tissues from a pregnancy are passed completely. In other cases, a D&C is necessary to ensure that all of it has been passed. (See "Patient information: Miscarriage").

Abortion — A D&C can be done to remove the contents of the uterus when a woman chooses to end a pregnancy.

Treatment of molar pregnancies — A molar pregnancy occurs when a tumor forms in place of normal pregnancy placenta.

Prolonged or excessive vaginal bleeding — D&C may be done as a treatment in some cases of prolonged or excessive vaginal bleeding. (See "Patient information: Abnormal uterine bleeding").

Postpartum hemorrhage — Curettage may be done to manage excessive bleeding after delivery of an infant (postpartum hemorrhage).

PREPARING FOR D&C — Some patients will need to have blood testing before D&C (such as a blood count), although this is not always necessary. Patients should not eat or drink anything before the procedure. All patients will need someone to accompany them home before or after receiving anesthesia, which causes sedation.

Some patients will need to have a device or medication placed in the cervix the day before their procedure. The purpose is to dilate the cervical opening, reducing the risk of cervical injury. Devices are used when the cervix must be dilated to a larger size than it would naturally be with pregnancy terminations and some types of hysteroscopy. Some patients will be instructed to insert a medicine...
cervix prior to the procedure.

After arriving for the procedure, a nurse may place an intravenous (IV) line, which can be used to give fluids and medicine during the procedure. The nurse or doctor will review the patient's medical history, list of medications used, and any drug allergies.

PROCEDURE — D&C can be performed in an operating room in a hospital or clinic. Many patients have a D&C performed in the hospital if they are pregnant or have uterine abnormalities. Woman's blood pressure, pulse, and blood oxygen levels are monitored during the procedure. The procedure takes 15 to 30 minutes.

Anesthesia — The procedure can be done using general, regional, or local (paracervical) block anesthesia. The type of anesthesia is based on the reason for the procedure as well as the medical history.

General anesthesia — General anesthesia induces sleep and completely relaxes the muscles, which makes it easier for the woman to be examined.

Regional anesthesia — Reginonal anesthesia uses an injection of an anesthetic into the area around the spinal cord to relax the muscles for surgery. The patient may be sedated with medicine given through an intravenous (IV) line.

Paracervical block — Anesthetic agents are injected directly into and around the cervix, numbing the area. The woman may have an IV line.

POST-PROCEDURE CARE — After the procedure, the patient will be cared for in a recovery or post-anesthesia care unit for about 45 minutes to monitor for excessive vaginal bleeding or other complications, and allows time for recovery from the anesthesia. Patients often have nausea and vomiting, which can be treated with medications.

Most patients should be able to resume their regular activities within a day or two. Mild cramping and spotting may occur and can be treated with nonsteroidal antiinflammatory medications such as ibuprofen (Advil®, Motrin®). Patients should not use tampons or douches during this time and should ask when they can safely have sexual intercourse. The next menstrual period may occur weeks after the procedure.

A woman should call her physician if she develops fever (temperature greater than 100.4°F), cramps lasting longer than 48 hours, or decreasing pain, prolonged or heavy bleeding, or foul-smelling vaginal discharge.

COMPLICATIONS — D&C is a commonly performed procedure that is usually very safe. Yet as with any operation, complications can occur.

D&C can include:

Uterine perforation — Uterine perforation occurs when one of the surgical instruments makes a hole in the uterus. It is most likely to occur during pregnancy due to softening of the uterine wall.

Fortunately, most uterine perforations heal on their own and do not require any treatment. Two potential problems caused by the perforation are injury to a blood vessel and injury to other internal organs. A second procedure may be needed to repair these types of injury.

Cervical injury — Injuries to the cervix can occur during dilation or from trauma related to the curettage. Lacerations (cuts) of the cervix can be treated with pressure to the area, application of medications that help stop bleeding, or in some cases, stitches in the cervix.

Infection — Infection from D&C is rare.

Intrauterine adhesions — Adhesions (areas of scar tissue) can sometimes form in the uterus following D&C. Adhesion is more likely to occur in women who have had a uterine abortion or were pregnant for a long time. In some cases, this can lead to abnormalities in the menstrual cycle, painful menstruation, and infertility. If adhesions are extensive, a woman can be treated with hormones to encourage growth of healthy uterine tissue. Adhesions can sometimes be removed with a surgical procedure.

WHERE TO GET MORE INFORMATION — Your healthcare provider is the best source of information for questions and concerns. Because no two patients are exactly alike and recommendations can vary from one person to another, it is important to talk to your provider who is familiar with your individual situation.

This discussion will be updated as needed every four months on our web site (www.uptodate.com/patients). Additional discussions written for healthcare professionals are also available for those who would like more detailed information.
