Reactive attachment disorder is a rare but serious condition in which an infant or young child doesn't establish healthy attachments with parents or caregivers. Reactive attachment disorder may develop if the child's basic needs for comfort, affection and nurturing aren't met and loving, caring, stable attachments with others are not established.

With treatment, children with reactive attachment disorder may develop more stable and healthy relationships with caregivers and others. Treatments for reactive attachment disorder include psychological counseling, parent or caregiver counseling and education, learning positive child and caregiver interactions, and creating a stable, nurturing environment.

Symptoms

Reactive attachment disorder can start in infancy. There's little research on signs and symptoms of reactive attachment disorder beyond early childhood, and it remains uncertain whether it occurs in children older than 5 years.

Signs and symptoms may include:

- Unexplained withdrawal, fear, sadness or irritability
- Sad and listless appearance
- Not seeking comfort or showing no response when comfort is given
Failure to smile

• Watching others closely but not engaging in social interaction
• Failing to ask for support or assistance
• Failure to reach out when picked up
• No interest in playing peekaboo or other interactive games

When to see a doctor

Consider getting an evaluation if your child shows any of the signs above. Signs can occur in children who don't have reactive attachment disorder or who have another disorder, such as autism spectrum disorder. It's important to have your child evaluated by a pediatric psychiatrist or psychologist who can determine whether such behaviors indicate a more serious problem.

Causes

To feel safe and develop trust, infants and young children need a stable, caring environment. Their basic emotional and physical needs must be consistently met. For instance, when a baby cries, the need for a meal or a diaper change must be met with a shared emotional exchange that may include eye contact, smiling and caressing.

A child whose needs are ignored or met with a lack of emotional response from caregivers does not come to expect care or comfort or form a stable attachment to caregivers.

It's not clear why some babies and children develop reactive attachment disorder and others don't. Various theories about reactive attachment disorder and its causes exist, and more research is needed to develop a better understanding and improve diagnosis and treatment options.

Risk factors

The risk of developing reactive attachment disorder from serious social and emotional neglect or the lack of opportunity to develop stable attachments may increase in children who, for example:
Live in a children's home or other institution

Frequently change foster homes or caregivers

Have parents who have severe mental health problems, criminal behavior or substance abuse that impairs their parenting

Have prolonged separation from parents or other caregivers due to hospitalization

However, most children who are severely neglected don't develop reactive attachment disorder.

Complications

Without treatment, reactive attachment disorder can continue for several years and may have lifelong consequences.

Some research suggests that some children and teenagers with reactive attachment disorder may display callous, unemotional traits that can include behavior problems and cruelty toward people or animals. However, more research is needed to determine if problems in older children and adults are related to experiences of reactive attachment disorder in early childhood.

Prevention

While it's not known with certainty if reactive attachment disorder can be prevented, there may be ways to reduce the risk of its development. Infants and young children need a stable, caring environment and their basic emotional and physical needs must be consistently met. The following parenting suggestions may help.
Take classes or volunteer with children if you lack experience or skill with babies or children. This will help you learn how to interact in a nurturing manner.

Be actively engaged with your child by lots of playing, talking to him or her, making eye contact, and smiling.

Learn to interpret your baby’s cues, such as different types of cries, so that you can meet his or her needs quickly and effectively.

Provide warm, nurturing interaction with your child, such as during feeding, bathing or changing diapers.

Offer both verbal and nonverbal responses to the child’s feelings through touch, facial expressions and tone of voice.
